

18 **Keywords:** Restoration Interdependencies, Hurricane Sandy, Scheduling

## 19 INTRODUCTION

20 The purpose of this work is to explore the new concept of *restoration interdependencies*  
21 that exist among infrastructures during their restoration efforts after an extreme event. Our  
22 particular focus is on this concept around Hurricane Sandy, which affected areas in and  
23 around New Jersey, New York City, and Long Island in late October 2012. The storm had  
24 significant effects on infrastructures in these areas; the United States Department of Energy  
25 Delivery and Reliability (2012) reports that at its peak, 2,097,933 customers were without  
26 power in New York, 2,615,291 customers were without power in New Jersey, 57 terminals  
27 associated with fuel distribution were closed, and refineries in the area lost around 40% of  
28 their operating capacity. Therefore, restoration of services provided by these infrastructures  
29 required a significant effort. Restoration interdependencies occur whenever a restoration  
30 task, process, or activity in one infrastructure is impacted by the restoration (or lack thereof)  
31 of another infrastructure. As an example, debris or flooding that blocks access into an area  
32 and prevents work crews from accessing damaged components of the power infrastructure is  
33 a restoration interdependency: the restoration of the damaged components is delayed due to  
34 the unavailability of roads (or, equivalently, lack of restoration) in the road network. This  
35 work: (i) identifies the examples of such restoration interdependencies as reported through  
36 major newspapers in the areas affected by Hurricane Sandy, (ii) provides a classification  
37 scheme for restoration interdependencies, and (iii) discusses the potential impact of them on  
38 post-event decision-making in infrastructure restoration.

39 The concept of *operational interdependencies* between critical infrastructure has been  
40 well-studied. Rinaldi et al. (2001), Little (2002), and Wallace et al. (2003) provide definitions  
41 and discussions of this concept. Operational interdependencies occur when a component of  
42 one infrastructure requires services provided by another infrastructure in order to properly  
43 function. These types of interdependencies can cause cascading failures (see, for example,  
44 McDaniels et al. 2007, Lee et al. 2007, and Chou and Tseng 2010) where the disruption of

45 services in one infrastructure causes disruptions and failures in other infrastructures that  
46 rely on its services. For example, disruptions in the power infrastructure could prevent  
47 a subway system from running all its scheduled routes, thereby disrupting transportation  
48 services provided by the subway. Mendonca and Wallace (2006) provide an overview of the  
49 operational interdependences observed after the terrorist attacks of September 11, 2001 on  
50 New York City’s critical infrastructure. Our work presents a similar overview of restoration  
51 interdependencies observed after Hurricane Sandy in the New York and New Jersey areas.

52 The concept of *infrastructure failure interdependencies* (IFIs) has also been studied by  
53 Chang et al. (2005), McDaniels et al. (2007), and McDaniels et al. (2009). McDaniels et al.  
54 (2007) define IFIs as “failures in interdependent infrastructure systems that are due to  
55 an initial infrastructure failure stemming from an extreme event.” These works examined a  
56 framework for IFIs by specifically focusing on them arising after large-scale disruptions to  
57 the power infrastructure, since this system is a critical lifeline for society (see, e.g., Reed  
58 et al. 2006). IFIs and restoration interdependencies are related in the sense that they arise  
59 after an extreme event impacts (a subset of) interdependent infrastructure systems. The  
60 distinguishing characteristic of restoration interdependencies is that there is a distinct *tem-*  
61 *poral element* associated with them since they focus on the restoration efforts of the systems  
62 as opposed to the consequences of an initial infrastructure failure.

63 The focus of this paper is on *restoration interdependencies* between infrastructure sys-  
64 tems after an extreme event. An *infrastructure* is broadly defined to be any system that  
65 provides services or delivers goods to the citizens of a society. This includes traditional civil  
66 infrastructures (such as power, natural gas, water, telecommunications, and transportation  
67 systems) that maintain and operate their own system as well as ‘social infrastructures’ (such  
68 as emergency medical services, a fuel supply chain, or a food supply chain) whose system  
69 relies on their own components (e.g., terminals and gas stations for a fuel supply chain) as  
70 well as civil infrastructure (e.g., the road system). This definition is line with the recent  
71 presidential initiative (The White House, Office of the President 2013) that defines 16 crit-

72 ical infrastructure sectors including ones with both civil (e.g., Transportation) and social  
73 (e.g., Healthcare) components. It is important to note that our work focuses on *specific*  
74 *infrastructures* within each sector rather than the sector as a whole (e.g., power instead of  
75 ‘Energy’). The Appendix includes a list of infrastructures that were observed to be involved  
76 in a restoration interdependency, broked down by the sector to which they belong.

77 The most basic type of restoration interdependency is related to the concept of op-  
78 erational interdependencies: a restoration task in an infrastructure relies on the services  
79 provided by another infrastructure. For example, after Hurricane Sandy, power was needed  
80 to pump out flooded subway stations in Manhattan. The pumps required power to operate,  
81 which could be supplied by either the power system or a portable generator. If power was  
82 available to an area where the pump was located, then this restoration task for the subway  
83 system could be conducted as planned. This type of interdependency is important in the  
84 sense that it bridges the gap between operational interdependencies and restoration interde-  
85 pendencies that link the restoration efforts of multiple infrastructures. However, it is unlikely  
86 that this interdependency would often be reported because it only affects a task in an in-  
87 frastructure’s restoration efforts when the required service is disrupted. This latter situation  
88 is more important since it links the restoration efforts across multiple infrastructures. In  
89 particular, the service must be restored in infrastructure A before the task in infrastructure  
90 B can be started. Therefore, the focus of our work will be on situations when restoration  
91 tasks across infrastructures are linked in terms of precedence or resource considerations.

92 Mathematical models have been developed to measure the reliability or the vulnerability  
93 of interdependent systems, including predicting cascading failures based on damage to the  
94 systems, see, for example, Dueñas-Osorio et al. (2007), Barker and Haines (2009a), Barker  
95 and Haines (2009b), Winkler et al. (2011), and Ouyang and Dueñas-Osorio (2011). A com-  
96 mon modeling approach is to view infrastructures as *networks* and examine their topological  
97 features or view the *services* provided by them as flow in the network (for an overview of  
98 network flows, see Ahuja et al. 1993). Lee et al. (2007) and Lee et al. (2009) provide network

99 modeling approaches to capture different classes of operational interdependencies that may  
100 exist between infrastructures. The models of Lee et al. (2007) and Lee et al. (2009) can be  
101 used to measure the level of disruptions throughout a set of interdependent infrastructures  
102 resulting from damage. In general, network models of the operations of infrastructures allow  
103 one to capture the services provided by the systems given a set of operational components.

104 There has also been work examining mathematical models to determine the restoration  
105 (or recovery) efforts of an infrastructure in response to damage that was caused by an ex-  
106 treme event. Guha et al. (1999), Ang (2006), Xu et al. (2007), Coffrin et al. (2011), and  
107 Nurre et al. (2012) present models for the restoration of a power infrastructure. Cagnan and  
108 Davidson (2003) present a simulation-based approach for restoring power and water systems.  
109 Matisziw et al. (2010) present a model for restoring infrastructures, such as telecommunica-  
110 tions, where connectivity between components is important. Yan and Shih (2009) and Stilp  
111 et al. (2012) focus on debris clearance operations in the transportation (road) infrastructure.  
112 Shoji and Toyota (2009) examine graph theory-based qualitative methods to understand  
113 the restoration process of interdependent infrastructure systems. Cavdaroglu et al. (2013)  
114 present a model for the restoration efforts in a single infrastructure that considers its oper-  
115 ational interdependencies with other infrastructures. An important aspect of many of these  
116 models is to recognize that scarce resources (such as work crews) need to be allocated to  
117 restoration activities, tasks, or processes over time. Therefore, these models focus on *schedul-*  
118 *ing* the restoration efforts of the infrastructure. The network models of infrastructures then  
119 play an important role in these scheduling models since they allow for an assessment of the  
120 operations of an infrastructure based on the set of operational components (which include  
121 repairs done to the infrastructure) at any point in time.

122 Restoration efforts, by their nature, involve scheduling ‘resources’ to activities that restore  
123 or repair damaged components in an infrastructure, install new (temporary) components  
124 within an infrastructure, or produce some level of functionality within the infrastructure.  
125 The term ‘resource’ is broadly defined in the sense they could model work crews, machines

126 (e.g., pumps or generators), or individual personnel. Much like how the operations of in-  
127 frastructures depend on other infrastructures, the restoration efforts of an infrastructure are  
128 impacted by the restoration efforts of other infrastructures. The focus of this paper is to  
129 identify, classify, and discuss the role of these restoration interdependencies which are defined  
130 as:

131 **Definition:** A *restoration interdependency* occurs when a restoration task, process,  
132 or activity in an infrastructure is impacted by a restoration task, process, or activity  
133 (or lack thereof) in a different infrastructure.

134 This definition is based on the broad interpretation of a restoration task meaning any  
135 task, process, or activity that is done in order to restore an infrastructure back to normal  
136 operating conditions (or an equivalent state). It is important to note that when a restoration  
137 task (such as pumping out a flooded subway tunnel) of an initial infrastructure requires  
138 the disrupted services provided by another infrastructure (such as power), this situation  
139 constitutes a restoration interdependency. This is because the timing of the restoration task  
140 in the initial infrastructure is impacted by when the restoration of services to the impacted  
141 area is completed by the other infrastructure. The key aspect of this situation for it to  
142 be classified as a restoration interdependency is that *the restoration efforts* of the initial  
143 infrastructure are impacted by the disruption of services and, equivalently, the timing of the  
144 restoration of these services by the other infrastructure.

145 Restoration interdependencies can, to a certain extent, link the restoration efforts of mul-  
146 tiple infrastructures. Therefore, the schedule of restoration efforts of an infrastructure may be  
147 impacted by its restoration interdependencies. For example, a precedence interdependency  
148 may force a scheduled restoration task in an infrastructure to be delayed since a restoration  
149 task in another infrastructure needs to be completed beforehand. Certain restoration in-  
150 terdependencies are closely tied to concepts such as precedence constraints from the field of  
151 scheduling (see Pinedo 2012 for an overview) with one important distinction: in a traditional

152 scheduling problem, all available scheduling resources are controlled by a central decision-  
153 maker. However, in the case of infrastructure restoration, the scheduling resources are often  
154 controlled by different infrastructures, private sector companies, public sector agencies, and  
155 the government. This means an understanding of the restoration interdependencies may  
156 help to better understand the level of communication and/or coordination required across  
157 sectors in responding to an extreme event.

## 158 **COMPARISON OF RESTORATION, OPERATIONAL, AND FAILURE**

### 159 **INTERDEPENDENCIES**

160 It is important to discuss and differentiate *restoration interdependencies* from the well-  
161 studied concepts of *operational interdependencies* and *infrastructure failure interdependencies*  
162 (IFIs). There are certain situations in which restoration tasks in a particular infrastructure  
163 affect when *services* provided by another infrastructure are restored but do not necessarily  
164 impact the restoration efforts of this other infrastructure. This would imply an operational  
165 interdependency but not a restoration interdependency. The focus of this section is to present  
166 some examples, in the context of Hurricane Sandy, to illustrate these differences.

167 For example, the subway system needs power to its components in order for trains to  
168 run their scheduled routes. Therefore, damage to a substation in the power system that  
169 provides power to a subset of subway components would cause a disruption of subway ser-  
170 vices. Therefore, subway services would not be restored until power restoration work crews  
171 repair the damaged substation and thus restore power to subway components. This situ-  
172 ation represents an operational interdependency: the operations of the subway system are  
173 dependent on the services provided by the power system. Further, the *disruption* of services  
174 provided by the subway system constitutes an infrastructure failure interdependency since  
175 the initial failure in the power infrastructure caused a failure in the subway system. This  
176 would not constitute a restoration interdependency because there were no restoration tasks  
177 in the subway system that were dependent on power.

178 However, there were restoration tasks in the subway system after Hurricane Sandy that

179 were dependent on power. For example, Flegenhimer (2012) discusses that test trains  
180 needed to be run in the subway system prior to running scheduled routes (to test the repairs  
181 done in the subway system). The running of test trains would be a restoration task in the  
182 subway system since it was an activity that needed to be done to restore the subway back  
183 to normal operating conditions after Hurricane Sandy. Therefore, this would constitute a  
184 restoration interdependency between the subway system and the power system: test trains  
185 could not be run (the restoration task in the subway system) until power was restored to  
186 the subway system (a restoration task in the power infrastructure).

187 Another example with the subway and power system was that the water in the subway  
188 needed to be pumped out before damage could be assessed and repaired in the system. This  
189 restoration task could not begin until either power was restored to an area (a restoration  
190 task in the power infrastructure) or until a generator and fuel were brought to the sub-  
191 way (a restoration task in the subway infrastructure). This represents a different type of  
192 restoration interdependency than the previous example since there are options for the which  
193 infrastructure needs to complete a task before the pumping task can begin.

194 As previously noted, the ‘simplest’ class of restoration interdependencies is when a  
195 restoration task in an infrastructure requires the *services* provided by another infrastruc-  
196 ture. This class will not be as frequently reported (if at all) since the restoration task goes  
197 off without any delay if the required services are available. Therefore, this work focuses on  
198 situations where restoration tasks and efforts are linked across multiple infrastructures. The  
199 most common situation that was observed for this simple class is when a restoration task  
200 within an infrastructure required the services provided by ‘first-responder’ infrastructures  
201 such as the police, fire, and EMS infrastructures. For example, police escorted power crews  
202 during their restoration activities to prevent harassing behavior (Santora 2012), were posted  
203 at intersections whose lights were out to help the operations of the road network, and were  
204 posted at gas stations in New Jersey and New York as they re-opened to control the lines  
205 and the crowds. These activities should be viewed as part of the services provided by the

206 police infrastructure since their daily operations are focused on the safety of citizenry and  
207 maintaining order. Similarly, firefighters needed to respond to fires caused by the event, help  
208 people evacuate areas that were subjected to severe flooding, and perform search and rescue  
209 missions as part of their ‘normal’ operations.

210 It is also important to note that during the initial aftermath of an event like Hurricane  
211 Sandy, people are searching for relevant information about the effects of it. Therefore,  
212 trusted news sources, such as newspapers and other reputable agencies, can help deliver  
213 this information to the local population, including delivering outage information to other  
214 infrastructures. However, these news sources can also suffer from this simplest class of  
215 restoration interdependencies. Without power, The Star Ledger, the main newspaper in  
216 New Jersey, was not able to print and its updates to its webpage came through “dictating  
217 stories to sister papers across the country” (Star Ledger Staff 2012). This means that the  
218 service provided by The Star Ledger would have been more effectively provided had power  
219 been restored to its main offices.

## 220 **METHODS FOR IDENTIFICATION OF RESTORATION INTERDEPENDENCIES**

221 The purpose of this section is to describe the methods used to identify restoration inter-  
222 dependencies. The intent of our analysis is to document observed examples of restoration  
223 interdependencies and provide a classification scheme of them. The focus of the identifica-  
224 tion process to determine examples was on the online versions of major newspapers in the  
225 areas affected by Hurricane Sandy. This focus was selected to ensure that the news articles  
226 were reputable and had proper protocols in place when collecting information to publish the  
227 articles. It is further important to note that our focus is on observations associated with the  
228 existence of a restoration interdependency as opposed to data surrounding it (for example,  
229 how long it took before the restoration interdependency was known to all infrastructures in-  
230 volved). Therefore, errors in reporting the data associated with the incident are very unlikely  
231 to impact this work.

232 The newspapers that were selected and the areas that they represent are: The New

233 York Times (New York City), Newsday (Long Island), The Star Ledger (New Jersey), and  
234 The Philadelphia Inquirer (South New Jersey and Philadelphia). The online versions of  
235 some of these newspapers are essentially a collaboration between themselves and other local  
236 newspapers, so our investigation went beyond these 4 newspapers. We specifically focused  
237 our search on articles that appeared in these newspapers (or their online presence) within  
238 three months of Hurricane Sandy’s landfall - from October 29, 2012 to January 31, 2013.

239 These newspapers had either an entire section devoted to Hurricane Sandy or an article  
240 tag of Hurricane Sandy that could be utilized to identify all articles posted relevant to  
241 Hurricane Sandy. These sections (or the tag search) would bring up a list of articles related  
242 to Hurricane Sandy and the titles of these articles helped determine whether they could  
243 potentially discuss restoration interdependencies. Based on the titles, an initial cut was  
244 made to articles that clearly did not discuss restoration activities. For example, articles that  
245 focused on benefit concerts or dinners would be cut and not read. If the title was deemed to  
246 potentially discuss restoration activities after Hurricane Sandy, it was then reviewed and, if  
247 applicable, quotes were identified that discussed potential restoration interdependencies. If  
248 quotes were identified, the articles were saved and recorded into a database.

249 We now discuss specific details about each of the newspapers used for this work. In  
250 particular, we discuss how we identified all Hurricane Sandy related articles and also the  
251 relationships between the online version of the newspapers and other local papers. These  
252 details are:

- 253 • **The New York Times:** The online version can be accessed at [www.nytimes.com](http://www.nytimes.com).  
254 There is specific section under “Times Topics” for “Hurricanes and Tropical Storms”  
255 that listed all articles with a tag of Hurricane Sandy.
- 256 • **Newsday:** The online version can be accessed at [www.newsday.com](http://www.newsday.com). There is a  
257 section dedicated to Hurricane Sandy at [www.newsday.com/long-island/sandy](http://www.newsday.com/long-island/sandy). The  
258 articles within this section are grouped by specific areas, such as “Long Island Recov-  
259 ers” and “Latest on LIPA” (LIPA is Long Island Power Authority), which helped in

260 identifying appropriate articles discussing restoration efforts.

- 261 • **Star Ledger:** The online version can be accessed at [www.nj.com](http://www.nj.com). There is a specific  
262 section on the site dedicated to Sandy at [www.nj.com/hurricanesandy/](http://www.nj.com/hurricanesandy/). After clicking  
263 on ‘Load More’ a few times, an option appears that allowed for an exploration of  
264 articles relevant to Hurricane Sandy by publication month. This site is a collaboration  
265 between the Star Ledger and local newspapers throughout New Jersey, hence reporters  
266 from all associated newspapers post articles to the site. There were many relevant  
267 articles from local newspapers, so we included an ‘Other NJ Papers’ source in our  
268 classification.
- 269 • **Philadelphia Inquirer:** The online version can be accessed at [www.philly.com](http://www.philly.com).  
270 This site is a collaboration with the Philadelphia Daily News, hence reporters from  
271 both newspapers post articles to the site. A search was conducted with the keyword  
272 “Hurricane Sandy” to access relevant articles on the site.

273 Through this process, a database of 331 potentially relevant quotes were collected from  
274 175 articles. A coding scheme was developed to then classify different types of restoration  
275 interdependencies. We note that not all quotes ended up concerning a restoration interde-  
276 pendency, so they were omitted from our observations. This was often due to the quote  
277 discussing an operational interdependency (e.g., a subway line was not running due to lack  
278 of power) as opposed to a restoration interdependency. We also note that multiple quotes  
279 may be associated with the same incident reported on by different sources. Using the coding  
280 scheme, a person classified all quotes into different classes of restoration interdependencies  
281 (including a ‘not relevant’ classification) resulting in a total of 96 quotes dealing with ob-  
282 served restoration interdependencies. Another person went through a random sampling of  
283 10% of the quotes in order to test the consistency of the coding scheme. This person’s  
284 classification matched (100% agreement) that of the original classification, validating the  
285 consistency of the coding scheme.

## 286 CLASSIFICATION OF RESTORATION INTERDEPENDENCIES

287 The focus of this section is on presenting the classes of restoration interdependencies  
288 identified from the various newspaper articles. The different classes of restoration interde-  
289 pendencies fall into one of two broad categories: time-based interdependencies (which are  
290 the traditional precedence, effectiveness precedence, options precedence, and time-sensitive  
291 options classes) and resource-based interdependencies (which is the competition for resources  
292 class). The time-based interdependencies typically concern the timing of restoration tasks  
293 across infrastructures while the resource-based interdependencies concern how restoration  
294 resources are distributed across infrastructures. For each specific restoration interdepen-  
295 dency class, its definition will be provided and a few illustrative examples, from Hurricane  
296 Sandy, will be discussed. In addition, Table 1 provides an overview of which restoration  
297 interdependencies were observed between different types of infrastructures. The entry in the  
298 table (Infrastructure A, Infrastructure B) provides all classes of restoration interdependen-  
299 cies between these two infrastructures as described below. A full list of infrastructures and  
300 their breakdown by critical infrastructure sectors appears in the Appendix.

### 301 **Traditional Precedence**

302 **Definition:** A restoration task in infrastructure B cannot be started until a restoration task  
303 in infrastructure A is complete.

304 **Observed Frequency:** 48.

305 **Examples (A, B):**

- 306 • (Power, Subway). The running of a test train in the subway system cannot start until  
307 power has been restored to the path of the test train (Flegenheimer 2012).
- 308 • (Port System, Fuel Supply Chain). The distribution of gas to restore normal levels  
309 of reserves at gas stations cannot start until debris is cleared from harbors and ports  
310 (Lipton and Krauss 2012, Hu 2012).
- 311 • (Power, Commercial Supply Chain). Assessment activities to determine damage to

312 production equipment at a facility cannot begin until power is restored to that facility  
313 (Associated Press 2012).

- 314 • (Residential, Power). Power can not be turned back on to a residence or commercial  
315 business until their electrical systems were assessed (Issler and Brodsky 2012).

316 **Discussion:** There were two main causes that led to the traditional precedence restoration  
317 interdependency: (i) the restoration task in infrastructure B required the restoration of  
318 disrupted services in infrastructure A and (ii) the restoration task in infrastructure A prevents  
319 the start of the restoration task in infrastructure B. Examples of the former include when  
320 power needs to be restored to test equipment in a commercial supply chain or the road  
321 system needs to allow for access to assess damaged components within the natural gas  
322 infrastructure. Examples of the latter include when the closing of a port prevents tankers  
323 carrying fuel (which will be used to restore reserves to normal levels) from delivering it  
324 through the port and when power work crews must clear and/or fix downed wires before  
325 downed trees can be cleared from a road.

326 The power infrastructure was involved as both infrastructure A and infrastructure B in  
327 many observed traditional precedence restoration interdependencies. There were situations  
328 where *components* in the power infrastructure needed to be safely moved or repaired prior to  
329 restoration tasks being started in other infrastructures (e.g., the repair of telecommunications  
330 lines needed power poles to be repaired). There were also situations when restoration tasks  
331 in other infrastructures needed the restoration of power to be completed. An interesting  
332 situation that arose with the power infrastructure after Hurricane Sandy was that residential  
333 neighborhoods which were flooded during the event would not have their power restored until  
334 the electrical systems of the houses were either inspected or switched off the grid.

### 335 **Effectiveness Precedence**

336 **Definition:** A restoration task in infrastructure B is not as effective (for example, it re-  
337 quires a longer processing time or more resources dedicated to it) until a restoration task in

338 infrastructure A is complete.

339 **Observed Frequency:** 8.

340 **Examples (A, B):**

- 341 • (Power, Subway). Pumping floodwaters from subway lines or tunnels is slowed by  
342 electrical shortages; thereby implying that restoring power to the appropriate area  
343 would speed up the pumping efforts (Flegenheimer and Leland 2012).
- 344 • (Power, Road System). The restoration of power to a pumping station would drain  
345 floodwaters from a road (Ma 2012).
- 346 • (Telecommunications, Fuel Supply Chain). Gas stations can only accept cash from  
347 customers due to disruptions with their credit card lines and communications systems  
348 (Hu and Yee 2012).

349 **Discussion:** The term ‘effectiveness’ is meant to be broad and improving effectiveness of the  
350 restoration task in infrastructure B after the completion of the task in infrastructure A can  
351 take a variety of forms. We observed situations where the processing time of a restoration  
352 task would decrease and situations where a restoration task would be made simpler (e.g.,  
353 a gas station accepting both credit cards and cash) by completing the restoration task in  
354 infrastructure A.

355 **Options Precedence**

356 **Definition:** A restoration task in infrastructure B can be completed by accomplishing a  
357 restoration task in one of a set of possible infrastructures,  $A_1, A_2, \dots, A_n$ .

358 **Observed Frequency:** 20.

359 **Examples ( $A_1, A_2, B$ ):**

- 360 • (*Power, Hospital, Hospital*). Bellevue Hospital lost both power and its backup gen-  
361 erators, but still needed to provide comfort and safety for its patients; this service  
362 could be provided by either power restoration to the hospital or the evacuation of the

363 patients from the hospital (Hartocollis and Bernstein 2012).

364 • (*Port System, Fuel Supply Chain, Fuel Supply Chain*). The distribution of gas to  
365 restore normal levels of reserves at gas stations can be accomplished by either repairing  
366 terminals and ports or dispatching trucks from out of state into the area (Hu and  
367 Krauss 2012).

368 • (*Power, Fuel Supply Chain, Fuel Supply Chain*). A gas station could reopen by either  
369 having its power restored or receiving a generator (Goldberg 2012).

370 **Discussion:** Many of the observed options restoration interdependencies typically involve  
371 how infrastructure B can deal with the disruption in services of another infrastructure.  
372 For example, a gas station in the fuel supply chain could either be supplied an emergency  
373 generator (a task in the fuel supply chain) or have its electrical power restored (a task in  
374 the power infrastructure) for the gas station to reopen. As another example, a hospital (or  
375 senior care facility) may need to restore its normal operations (i.e., providing comfort and  
376 safety to its patients) should its back-up generators fail and power is disrupted to it. This  
377 could be done by either evacuating their patients (a task in the hospital infrastructure) or  
378 power being restored (a task in the power infrastructure). It is likely that the frequency  
379 of this class is much higher than observed since whenever a restoration task in another  
380 infrastructure requires power and power is disrupted, the infrastructure has the option to  
381 either bring in a generator or wait for power to be restored.

### 382 **Time-Sensitive Options**

383 **Definition:** A restoration task in infrastructure B must be completed only if a restoration  
384 task in infrastructure A is not completed by a certain (unknown) deadline. Therefore, the  
385 restoration task in A must be completed by its deadline or the task in B must be completed.

386 **Observed Frequency:** 11.

387 **Examples (A, B):**

388 • (*Power, Wireless Telecommunications*). Power is not restored before a generator,

389 which powers a cell tower, runs out of fuel which creates a restoration task of refueling  
390 the generator within the telecommunications infrastructure (Stein 2012).

- 391 • (Road System, Residential). Firefighters cannot access a fire (thus providing emer-  
392 gency services) because flooding prevents access to the location of the fire, which  
393 allows the fire to spread and creates more residential cleanup tasks (Heyboer 2012).

394 **Discussion:** The most frequently reported situation for this restoration interdependency  
395 involved a situation where the deadline for the task in infrastructure A is unknown: a  
396 road system has not been restored by the time a fire starts (this time is unknown) and,  
397 therefore, the fire spreads to more residential areas. However, a situation that is probably  
398 more common, but less frequently reported, is one where if power is not restored by a certain  
399 time, the emergency generators of an infrastructure need to be refueled. This was observed  
400 for wireless telecommunications but could occur whenever an infrastructure system has its  
401 own backup generators (e.g., water or waste water treatment plants).

#### 402 **Competition for Resources**

403 **Definition:** Restoration tasks in infrastructures  $A_1, A_2, \dots, A_n$  compete for the same set  
404 of scarce resources.

405 **Observed Frequency:** 9.

406 **Examples ( $A_1, A_2, \dots, A_n$ ):**

- 407 • (Emergency (EMS) Services, Power). Emergency vehicles and power restoration crews  
408 both require fuel to aid their restoration activities (Nussbaum 2012).
- 409 • (Emergency Shelters, Public (Education) Services). Emergency shelters and educa-  
410 tional services compete for location-based resources, such as both being located at a  
411 school (Bernstein 2012).
- 412 • (Hospital, Water, Waste Water). The location of power generators brought into an  
413 area could assist with providing electricity to hospitals, the water system, or waste  
414 water treatment plants (Johnson 2012).

415 **Discussion:** It was common to observe that the infrastructures were competing for either  
416 generators or fuel. It could be argued that most infrastructures are competing with each  
417 other for the ‘fuel resource,’ especially given the shortages observed after Hurricane Sandy,  
418 since fuel is critical in moving personnel and other restoration resources to their desired  
419 locations. It is also possible that *personnel* are the resources for which the infrastructures  
420 are competing; for example, skilled arborists could be used by both the power infrastructure  
421 and the road system when clearing trees for their restoration activities.

## 422 **ANALYSIS OF OBSERVED RESTORATION INTERDEPENDENCIES**

423 The focus of this section is on providing analysis of the restoration interdependencies  
424 that were observed after Hurricane Sandy. First, the frequency of such restoration inter-  
425 dependencies (as observed by the number of quotes found in articles discussing them) are  
426 provided. We then provide a temporal analysis associated with the observed restoration  
427 interdependencies. Finally, we present the types of restoration interdependencies that were  
428 observed between the 16 critical infrastructure sectors defined by the U.S. Department of  
429 Homeland Security.

### 430 **Frequency Summary**

431 Table 2 provides the frequency of each of these different classes of restoration interde-  
432 dependencies based on the news articles found from each source. Overall, we observed 96  
433 instances that fit our coding scheme in defining and identifying restoration interdependen-  
434 cies. The traditional precedence restoration interdependency is by far the one that was most  
435 commonly discussed in the newspapers (48 instances); the options precedence restoration  
436 interdependency (20 instances) was the next most frequently reported.

### 437 **Temporal Analysis**

438 This section focuses on the temporal analysis of the observed restoration interdependen-  
439 cies. Figure 1 provides a timeline of the observed restoration interdependencies, broken  
440 down by type, during the first two weeks after Hurricane Sandy. Hurricane Sandy made

441 landfall in the areas where this study has focused on October 29, 2012 and 83 of 96 (86.5%)  
442 observed restoration interdependencies were reported during these first two weeks. It should  
443 be noted that many of the other 13 articles not covered in this figure are more overviews of  
444 the impacts of Hurricane Sandy and, therefore, do not necessarily report on incidents that  
445 have occurred well past the date of Sandy. The largest number of observations on a single  
446 day was 18 which were reported two days after the storm (on October 31, 2012) and the  
447 following day 16 observations were identified. Figure 1 demonstrates that there is a surge in  
448 the number of restoration interdependencies during the first few days after Hurricane Sandy  
449 and then the number becomes less significant a week past Hurricane Sandy.

450 One key point in the identification process is that a restoration interdependency will, typ-  
451 ically, not be reported until an infrastructure (or infrastructures) encounter the restoration  
452 interdependency. Therefore, we can obtain insights by examining the distribution of *when*  
453 certain classes of restoration interdependencies were observed. Figure 2 provides an analysis,  
454 for each class of restoration interdependencies, of the percentage of the total observations of  
455 that class that were obtained by a certain date. For example, roughly 9% of time-sensitive  
456 options observations were reported within 1 day of Hurricane Sandy, 63% were reported  
457 within 2 days, and 90% were reported within 8 days. This property can be attributed to the  
458 fact that many of the time-sensitive options observations encountered dealt with roadways  
459 blocking access to fires, which allowed them to spread and create more clean-up activities.  
460 Therefore, as roadways were cleared after the event, this type of incident became less fre-  
461 quent. The competition for resources interdependency also exhibits a rapid increase in these  
462 percentages within the first 7 days after the event, which can be attributed to the fact that  
463 as services are restored the resources that were necessary (e.g., fuel and generators) become  
464 more abundant.

465 The traditional, effectiveness, and options classes exhibit a more steady (e.g., closer to  
466 linear) trend in the growth of their percentage of observations as a function of time. This  
467 linear relationship has more to do with the time of *observation* of the interdependency

468 than the time of *occurrence* of the interdependency. For example, the reported incidents of  
469 the traditional precedence class imply that infrastructure B had resources to attempt the  
470 restoration task but it was prevented from starting due to its restoration interdependency.  
471 Therefore, with limited resources available for infrastructure restoration, it may be some  
472 time before a resource in infrastructure B could be allocated to attempt that particular  
473 restoration task and identify the restoration interdependency. The options precedence class  
474 has the property that the implemented option (often within infrastructure B) would not  
475 be selected until some time had passed and the restoration task in the other infrastructure  
476 had still not been completed. For example, if power was out to a nursing home or to a  
477 gas station, the nursing home or gas station may wait some time before evacuations (in the  
478 case of the nursing home) or obtaining a back-up generator (in the case of the gas station).  
479 Therefore, the time of the observed options precedence interdependency is often a function of  
480 the criticality of the restoration task in infrastructure B: the earliest observed ones from this  
481 class often dealt with hospitals throughout the area and how they restored their operations  
482 when faced with a lack of power (e.g., evacuating patients or setting up clinics elsewhere).

### 483 **Restoration Interdependencies and Critical Infrastructure Sectors**

484 The restoration interdependencies between the efforts of critical infrastructure sectors  
485 is important to understand in order to better plan for the level of coordination necessary  
486 for effective restoration efforts across all critical sectors after an extreme event. Table 3  
487 presents the types of observed restoration interdependencies between the 16 critical infras-  
488 tructure sectors as defined in the recent presidential initiative (The White House, Office of  
489 the President 2013). The entry in the table (Infrastructure Sector A, Infrastructure Sector B)  
490 provides all classes of restoration interdependencies between these two infrastructure sectors.  
491 For example, the entry (Energy, Transportation) lists Traditional Precedence, Effectiveness  
492 Precedence, and Competition for Resources. This implies that we observed a traditional  
493 precedence restoration interdependency and an effectiveness precedence restoration interde-  
494 pendency where an infrastructure in the Energy sector took the role of infrastructure A in the

495 definition and an infrastructure in the Transportation sector took the role of infrastructure  
496 B. In other words, there was a situation where some task in an infrastructure in the Energy  
497 sector needed to be completed prior to starting a restoration task in an infrastructure in the  
498 Transportation sector. In addition, we observed that a restoration task in an infrastructure  
499 in the Energy sector and a restoration task in an infrastructure in the Transportation sector  
500 competed for the same resource.

501 For time-based restoration interdependencies, the row provides the sector of the infras-  
502 tructure of a restoration task that affects the processing (either its effectiveness or starting  
503 time) of a restoration task in an infrastructure in the sector associated with the column. The  
504 Energy sector row (so it takes the role of infrastructure A) has 8 such precedence entries  
505 with other sectors: Communications, Critical Manufacturing, Emergency Services, Energy,  
506 Food and Agriculture, Government Facilities, Healthcare, and Transportation. It is also  
507 interesting to note that the Energy sector column (so it takes the role of infrastructure B in  
508 the definitions) has 4 such precedence entries. This could imply that the information from  
509 and communications with the restoration efforts of the Energy sector could be quite valuable  
510 in restoration efforts across sectors. For resource-based restoration interdependencies, there  
511 is no particular sector that stands out in terms of their observed resource relationships with  
512 other infrastructures.

## 513 **DISCUSSION OF RESTORATION INTERDEPENDENCIES AND THE** 514 **IMPORTANCE OF INFORMATION-SHARING**

515 Infrastructure managers are able to assess the damage done to their infrastructure by  
516 an extreme event and then plan their restoration efforts. Based on these planned efforts,  
517 the infrastructure manager can project out the set of operational components of their in-  
518 frastructure over time or, equivalently, project out what their infrastructure will look like.  
519 This set of operational components helps to predict the level of services provided by the  
520 infrastructure; however, operational interdependencies may affect this prediction since dis-  
521 ruptions of services in other infrastructures may affect the components of the infrastructure

522 under consideration. Therefore, understanding these operational interdependencies can help  
523 to better predict and understand the impact of an infrastructure’s restoration efforts on the  
524 services it provides to society.

525 In a similar manner, an understanding of restoration interdependencies can help to bet-  
526 ter predict and understand the timeline of an infrastructure’s restoration efforts. Based  
527 on the planned restoration efforts, an infrastructure manager can predict the set of opera-  
528 tional components in the infrastructure; i.e., they can predict when restoration tasks will  
529 be complete and change the set of operational components in their infrastructure. However,  
530 restoration interdependencies can impact this prediction since they can impact the planned  
531 start times of restoration tasks or impact the effectiveness of planned restoration tasks in  
532 the infrastructure under consideration.

533 The impact of restoration interdependencies on the effectiveness of an infrastructure’s  
534 restoration efforts could potentially be mitigated through either coordination or information-  
535 sharing between infrastructures. Restoration interdependencies will still affect the timeline  
536 of an infrastructure’s restoration efforts but the information-sharing would alleviate much  
537 of the uncertainty involved with the timeline. More importantly, information-sharing could  
538 help an infrastructure better formulate its restoration efforts by planning for the restoration  
539 interdependencies that will impact them. For example, an infrastructure could base its  
540 scheduling decisions (e.g., the sequencing of when crews will work on restoration tasks) on  
541 its known restoration interdependencies and when they would be alleviated. This would help  
542 to minimize ‘unforced’ idle time across the work crews that results in them waiting around  
543 for their next task to become available to be processed (e.g., a power crew waiting around  
544 for residential inspections to be complete) or, in adapting their schedule by relocating to  
545 another task (e.g., the power work crew realizes they will sit idle and then travels to another  
546 area to work - it would have been a better use of time for the workers to go directly to this  
547 next area).

548 Information-sharing would be especially important in planning restoration efforts of an

549 infrastructure that has multiple instances of the same type of restoration interdependencies  
550 with another infrastructure. As an example in the context of Hurricane Sandy, consider  
551 the subway system of lower Manhattan planning out restoration tasks to pump out water  
552 from its tunnels and stations. The pumping of a particular tunnel or station represents an  
553 options precedence relationship: the restoration task of pumping out a particular subway  
554 line requires either power to be restored to the area or a generator to be located in the area.  
555 The locations of the generators and their subsequent relocations are decisions involved in the  
556 planning of the subway system's restoration efforts. If pumps were located to pump water  
557 out of Station 1 and Station 2 and only one generator was available, information about the  
558 power restoration efforts would help plan the subway system's efforts more effectively. In  
559 particular, if both stations require the same amount of time to pump the water out, then  
560 the generator should be located at the station that will be without power.

561 It is unlikely that full coordination could be achieved across infrastructures due to the  
562 large number of public and private-sector agencies that must formulate restoration efforts  
563 after the event. This complicates the restoration of normal day-to-day operations of soci-  
564 ety after an event like Hurricane Sandy since multiple agencies are formulating their own  
565 (independent) restoration efforts. Each agency may be working towards the goal of full  
566 restoration but the lack of communication amongst them impacts the effectiveness of the  
567 restoration as a whole. The concept of information-sharing, where certain key agencies and  
568 infrastructures share their planned restoration efforts, can help to mitigate the impacts of  
569 our identified restoration interdependencies on the overall restoration efforts since infrastruc-  
570 tures can better plan for their impact. In addition, infrastructure managers could gain a  
571 better understanding of how the schedule of their restoration efforts impacts other infras-  
572 tructure's restoration planning and could, potentially, consider altering their efforts to help  
573 other infrastructures.

574 These forms of coordination and information-sharing should lead to improved restoration  
575 efforts, especially when considering restoration interdependencies. As a potential quantifica-

tion of this improvement, we can examine shifts in restoration times of services provided by infrastructures after Hurricane Sandy. As our first example, we focus on power restoration in New York City and in Long Island. Figure 3 (created using data from New York Independent System Operator 2012) provides the power load curve of these areas during October and November 2012. The focus of the shifts for these examples is on the *percentage* of the average load that occurred after Hurricane Sandy at a particular point in time. For example, if we are looking at the time stamp of Thursday, November 1 at 2 p.m., we examine the load in New York City and compare it to the *average* load of the three previous Thursday 2 p.m. time stamps in New York City. This comparison can then help to provide the percentage of ‘restored’ services by Thursday, November 1 at 2 p.m. This percentage, as a function of time, will typically increase (although it is imperfect because it is a function of consumer behavior). We can then quantify the improvement in restoration by examining shifts in *when* these percentages occur. For example, if Thursday at 2 p.m. had 90% of the average load, a 15 minute shift in average restoration time would imply that Thursday at 1:45 p.m. had 90% of *its* average load the previous three weeks. A shift of 15 minutes earlier in the average restoration time results in an increase of 2356 megawatt hours (MWh) of energy over the course of the week following Hurricane Sandy in New York City. A shift of 30 minutes earlier results in an increase of 3717 MWh of energy during the same time frame. We can put these increases into the context of ‘customer hours’ (e.g., a customer has power for one hour) to better understand the impact; the U.S. Energy Information Administration (2011) reports that the average residential customer in 2011 in the state of New York consumes 7332 kWh of power per year. This implies that one MWh would translate to 1195 ‘customer hours.’ Even assuming that only 50% of the increase in energy resulting from the shift goes to residential customers, the 15 minute shift would result in an increase of 1.4 million customer hours and the 30 minute shift would result in a shift of 2.2 million customer hours. This represents a significant amount of power during the city’s restoration efforts. For Long Island, a shift of restoration time by 15 and 30 minutes earlier results in an increase of 1161 MWh and 1765

603 MWh, respectively. This translates to .69 million customer hours and 1.1 million customer  
604 hours.

605 The second example in quantifying the improvement in restoration efforts through coor-  
606 dination or information-sharing is on the fuel supply chain. Major aspects of the restoration  
607 efforts of the fuel supply chain were ensuring that demand could be met at gas stations  
608 and appropriate inventory levels were reestablished after Hurricane Sandy. The U.S. Energy  
609 Information Administration (2012) provides a report on surveys of gas stations in the New  
610 York metropolitan area and the results suggest that disruptions to the supply of fuel was a  
611 significant reason for gas stations to be closed. The focus of this quantification is on shifting  
612 the restoration times of the *refineries* that feed the New York metropolitan area earlier.  
613 The United States Department of Energy Delivery and Reliability 2012 provides frequent  
614 reports about the status of all energy-related infrastructures and, in particular, the status of  
615 the 6 refineries in the area affected by Hurricane Sandy. The statuses that were reported are:  
616 ‘Shut Down’ (zero capacity), ‘Reduced Runs’ (which we assumed to be operating at 50%  
617 capacity), and ‘Normal’ (assumed to be operating at 100% capacity). These reports were in  
618 half-day increments and we focus on shifting the status of the refinery by a half day earlier  
619 when shifting restoration efforts earlier. This may be an unrealistic shift but was the best  
620 estimate that could be achieved due to the timing of the reports. This half-day restoration  
621 shift results in an increase of 131,800 barrels coming into the area over the course of the week  
622 following Hurricane Sandy. Given the demand for fuel after Hurricane Sandy, this increase  
623 would have helped the area in its restoration.

624 The next step for research on restoration interdependencies is to attempt to more pre-  
625 cisely *quantify* the impact of coordination and various forms of information-sharing. This  
626 will require examining models that focus on restoration efforts across infrastructures and ap-  
627 propriately incorporating the restoration interdependencies. The models that examine full  
628 coordination will blend the interdependent layered network model of Lee et al. (2007) that  
629 captures the performance of a set of interdependent infrastructure systems with scheduling

630 models (such as that of Nurre et al. 2012) for each infrastructure involved in the restoration  
631 efforts. These models would help to understand the best possible performance in the restora-  
632 tion across infrastructures. The role of information-sharing can be captured by appropriately  
633 altering scheduling models for restoring a single infrastructure to include the impact of known  
634 disruptions (and their length) and the restoration activities of other infrastructures.

## 806 **APPENDIX**

807 The purpose of this section is to provide the list of infrastructures that were observed to  
808 be involved in a restoration interdependency. This list of infrastructures is broken down by  
809 critical infrastructure sector, i.e., each infrastructure within a certain sector is presented in  
810 the same section.

### 811 **Commercial Facilities Sector**

812 Commercial Facilities

813 Residential

### 814 **Communications Sector**

815 Telecommunications

816 Wireless Telecommunications

817 **Critical Manufacturing Sector**

818 Commercial Supply Chain

819 **Emergency Services Sector**

820 Emergency (EMS) Services

821 Emergency (Fire) Services

822 Emergency (Police) Services

823 Emergency Shelters

824 Public (Emergency Operations Center) Services

825 **Energy Sector**

826 Fuel Supply Chain

827 Natural Gas Infrastructure

828 Power

829 **Financial Services Sector**

830 Financial Services

831 **Food and Agriculture Sector**

832 Necessity (Food) Supply Chain

833 **Government Facilities Sector**

834 Public (Education) Services

835 **Healthcare Sector**

836 Hospital

837 Senior Care Facilities

838 **Transportation Sector**

839 Port System

840 Road System

841 Subway

842 **Water and Wastewater Sector**

843 Water

844 Waste Water
